

Aircraft Development: Problems & Failures A Design Issue ?

$$C_D = C_{D0}(Mach, H) + C_{DF}(C_L - C_{L0}, Mach)$$

$$e = \frac{(C_L - C_{L0})^2}{\pi A C_{DF}}$$

$$C_D = n_{drag} \left[C_{D0}(M, h) + C_{DF}(C_L, C_{Lmin}, M) + \sum_{storage} \frac{S_{ref}^{(i)}}{S_{ref}} \right]$$

$$D = \frac{\rho}{2} v^2 C_D S_{ref}$$

$$n = \sqrt{\frac{(v_{rate})^2}{g} - 1}$$

$$mv\dot{\gamma} + D - T \cos(\alpha + \sigma) + mg \sin(\gamma) = 0$$

$$-mv\dot{\alpha} + L + T \sin(\alpha + \sigma) - mg \cos(\gamma) = 0$$

AIRTEC 2014
 Frankfurt, 27-29 October

Dr. Georges Bridel
 Managing Director, ALR Zurich / Switzerland

Project problems & failures, the designers main responsibility?

$$C_D = C_{D0}(Mach, H) + C_{Di}(C_L - C_{L0}, Mach)$$

$$q = \frac{C_L - C_{L0}}{C_D}$$

$$C_{L_{max}}(M) + \sum_{\text{aircraft}} \frac{\Delta S_{max}(M)}{S_{ref}}$$

$$mv + D - T \cos(\alpha + \sigma) + mg \sin(\gamma) = 0$$

$$-mv\dot{\gamma} + L + T \sin(\alpha + \sigma) - mg \cos(\gamma) = 0$$

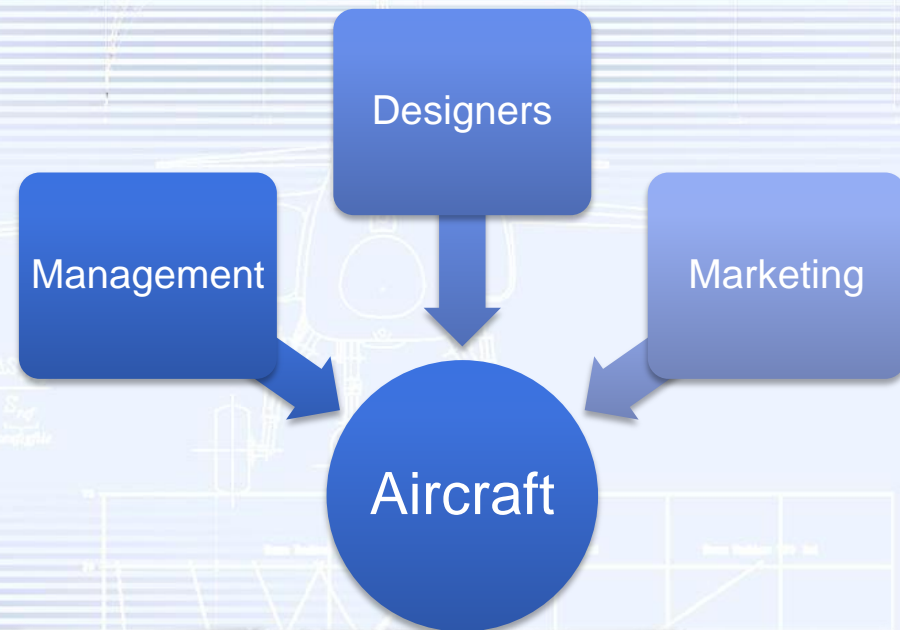

Survey:

An approach from history and from experience

Responsibilities for project problems & failures:

- The **designers** to be blamed?
- The **marketing**?
- „The **management**“?
- Unforseeable: industrial/design challenges?
- Changes in market, technologies, tools?
- Politics? (industrial, national/international)

Developments ended after initial success

- **Airships:** long-range air transportation during 15 years, „Hindenburg“ as catalyst:
 - Basic operational-technical problems.
 - Superseded by technical capabilities of fixed wing a/c
- **Transatlantic flying boats:** transformation of sea-traffic to air:
 - Superseded by technique of land-based planes
 - Less suitable in operations, limited „footprint“ (T/O & landing sites), no revival (Do)
- **Concorde / Supersonic Transport:**
 - Technical/operational success
 - Excessive operational cost, limited market (transatlantic), environment

Developments not in phase with market / too specific application

UK Developments, after great successes (WWII)

- **Airliners 1950-1965:** Trident, VC-10, BAC-111
 - Targeted for singular local airlines, ignoring world market
 - Fractioned industry structures, limited & dispersed capabilities
- **Total program failures:**
 - TSR 2 & Nimrod AEW
 - Cost, time, organisation, design/technical
- **Co-operation programs (Tornado, EF):**
 - Program successes, but too complex management and coordination structures
- Small market, fragmented industry, cost, design requirements
- Co-operative design programs: beyond the limits now
- Design responsibility in one hand, Airbus' tremendous success!
- Future European „military air“? One single*, merged company!

(*instead of five..)

Development Today: Learning from the Past?

- **Airbus A400M**

- Existing knowledge and capability ignored (Antonov 70)
- Re-installed European capability (airframe, engine...)
- Cost-increase by +50%, delay +60%

- **F-35 Lightning II**

- 3 variants of basic design (failed already with the F-111)
- Cost-increase by +100%, delay +80% (today...)

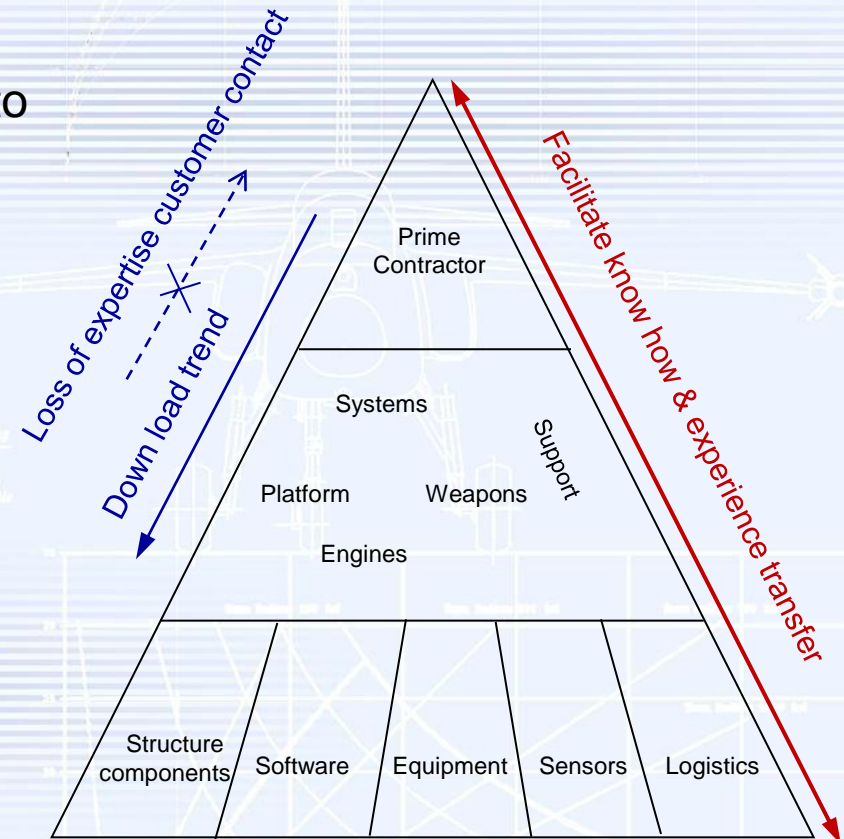

- Unrealistic program start: knowledge & capability
- Too many (exotic) requirements in one single program
- Too big to fail: survived with political and economic power

Vertical Integration, The Dangers

- System design & integration downloaded to component level / smaller units
- Prime contractor design & production experience & control under threat
- Span between programmes, loss of specialists

Measure (among others):
Maintaining know-how by engaging highly experienced specialists beyond retirement
(Experience of ALR in conceptual design and operations analysis)

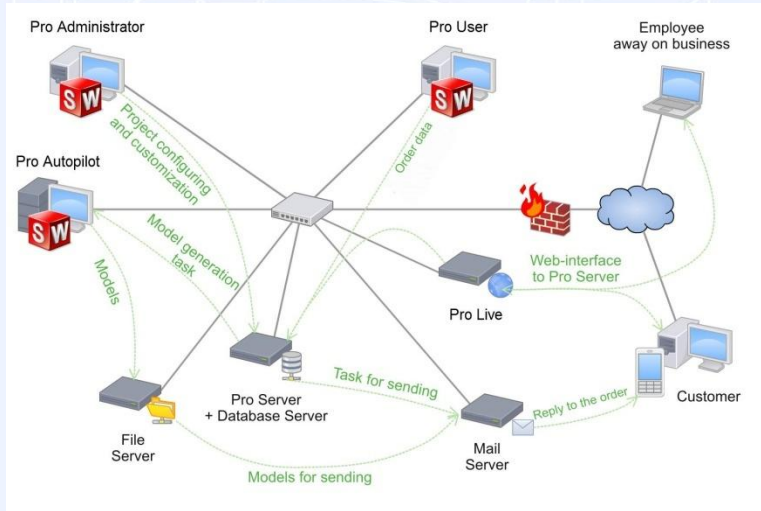

Design, Engineering & Management Capability

(US Data 2000)

typical staff career today: working on 1 program only

New Design Processes & Engineering Tools

Automated design tool

(Credit to Pavel Zhuravlev, Moscow)

Mechanical Turk or Automaton Chess Player, 1770 (Vienna, Maria-Theresia)

Mechanical illusion that allowed a human chess master hiding inside to operate the machine

Yes, but...

will not replace experience, top experts and generalists

Concluding Aspects

- Understanding requirements is fundamental (designer **and** customer)
- Quality of concept design, early investment is essential
- Past experience must be fully integrated, knowledge transfer tools? Integrate retired/experienced staff
- New design/development/management tools: to enhance design process, not to replace long-term experience
- Tools often developed for existing/past programs. The new?
- Co-operative programs beyond the limits, restore leadership & authority, similar to the past chief designers (not same role)

Designers not to be blamed, program set-up is fundamental!

(initial aspects, more detailed analysis planned)

Appendix: The Technology Issue (mainly military)

- Demonstrated, too early application, enabling technologies not mature
 - VTOL Germany (VJ-101, VAK 191) engines and system technology , Requirements disappeared
 - Laminar Flow Technology (1980ies, 1990ies, 2000+)
 - Ultrafan-propulsion technology
- Re-invented because forgotten:
 - Weapons- and payload bay: European technology development despite early experience (transonic Buccaneer, V-bombers etc.)
 - Laminar Flow: no knowledge transfer, IPR issues
- Application in products:
 - Mismatch between marketing – management – engineering
- Fragmented European military landscape
 - Efforts from 5 aircraft-, 3 system- 2 engine-companies, parallel & wasted
 - Almost no European projects : ETAP (European Technology Acquisition Programme);
EDA (European Defence Agency) , under-funded! Constant IPR problems
